TURBO CHARGE YOUR IIe AND EXPAND APPLE WORKS TO 101K

MEMORYMASTER IIe™ 128K RAM CARD

As an Apple user, you already know all the things your IIe can do. Now Applied Engineering expands that list with MemoryMaster IIe™.

With the MemoryMaster IIe, you'll have up to 192K RAM at your command. Designed expressly for the auxiliary slot in the IIe, the MemoryMaster IIe provides an 80 column video display and up to 128K of memory using just one slot. But the MemoryMaster IIe differs from other large memory cards in one important way, both the 64K and 128K configurations are TOTALLY compatible with software written for the Apple IIe 80 column and extended 80 column cards. In fact, it's not possible to write a program that uses the smaller cards from Apple that won't work with the MemoryMaster IIe.

But the MemoryMaster IIe is not just another piece of unsupported

hardware. Each MemoryMaster IIe includes a multi-programming environment program which will enable you to have three different programs ready to run at any moment.

Many of today's software packages for data-base management, word processing, business applications and spread sheets either require or are enhanced by the MemoryMaster IIe. And more and more programs are using double high resolution graphics for which the MemoryMaster IIe is required.

If you already have Apple's 64K card, just order the MemoryMaster IIe with 64K and use the 64K from your old board to give you a full 128K. The board is fully socketed so you simply plug in your chips.

- Expands your Apple IIe to 192K memory.
- Provides an 80 column text display.
- TOTALLY compatible with all Apple IIe 80 column and extended 80 column card software—there are NO exceptions.
- Available in 64K and 128K configurations.
- The 64K configuration is USER upgradeable to 128K.
- Can be used as a solid state disk drive to make your programs run over 20 times faster (the 64K configuration will act as half a drive).
- Bank select LED's for each 64K bank.
- Permits your IIe to use double high resolution graphics.
- Uses the same commands as the Apple 80 column card.
- Plugs into the auxiliary slot in the Apple IIe.
- The 64K MemoryMaster IIe will automatically expand VisiCalc to 95K storage, in 80 columns! The 128K MemoryMaster IIe will expand VisiCalc to 141K storage with optional pre-boot disk.
- The 64K MemoryMaster IIe will automatically expand Apple Works to 55K storage, in 80 columns! The 128K MemoryMaster IIe will expand Apple Works to 101K storage with optional expand disk.
- Fully PASCAL and CP/M compatible.
- Lowest power consuming 128K card available.
- Complete documentation included.
- PRO-DOS will automatically use the MemoryMaster IIe as a high speed disk drive.
- Three year warranty.

Low Cost Options.

Apple Works Expand™

Although Apple Works is compatible with both a 64K and 128K MemoryMaster IIe, Apple Works only "sees" it's first 64K bank. Our Apple Works expand program will make a modification to Apple Works that simply lets it know you've got more memory, giving you 101K work space.

\$29

Ram Drive IIe™

Sure-fire wait-reduction! Time was, you had to wait for your disk drives. But Ram Drive IIe has changed all that, giving you a large, extremely fast, solid-state disk drive, much faster than floppies or hard disks.

Ram Drive IIe works with either the 64K or 128K MemoryMaster IIe to give you a high speed solid-state disk drive. The Ram Drive IIe software features audio-visual access indicators, easy setup for turnkey operation, and easy menu driven documentation. The program can be modified and is copyable. If you have a 64K MemoryMaster, Ram Drive IIe will act as half a disk drive. If you have a 128K MemoryMaster, Ram Drive IIe will act as a full disk drive. Ram Drive IIe is compatible with APPLESOFT, DOS3.3, PRO-DOS, and PASCAL. Disk also includes a high speed RAM disk copying program. Ram Drive is another disk drive only 20 times faster.

\$29

CP/M Ram Drive IIe

CP/M Ram Drive IIe is just like the Ram Drive IIe above, only for CP/M. CP/M Ram Drive IIe runs on any Z-80 card that runs standard CP/M i.e. Applied Engineering Z-80 Plus or Microsoft Soft Card. CP/M Ram Drive will dramatically speed up the operation of most CP/M software because CP/M normally goes to disk fairly often. Fast acting software like dBase II and Wordstar become virtually instantaneous when used with CP/M Ram Drive.

\$29

VC IIe Expander

VC IIe Expander will give owners of VisiCalc IIe and the 128K MemoryMaster a total of 141K work space. This disk will pre-boot VC IIe in 1.5 seconds.

\$29

Advanced VC IIe Expander

Advanced VC IIe Expander is just like VC IIe Expand only it is designed for Advanced VC IIe. Your work space will be increased to 131K. This disk will pre-boot in 1.5 seconds.

\$29

MEMORYMASTER IIe with 128K	\$249
Upgradeable MEMORYMASTER IIe with 64K	\$169
A. E. Extended 80 Column Card with 64K	\$139

★ SPECIAL OFFERS ★

(Limited time only)
Order now!!!

S1 EAMON Collectors Offer

Every EAMON scenario and all EAMON utilities. Includes E1 through E76, U1 through U4, D5, D6. *82 EAMON volumes for only \$250.*

EAMON adventures are fantasy role-playing games. Your character, which you create using the Master Disk, wanders through a fantasy world full of dangers and rewards. You are the master of your own fate; the course of the adventure is of your own making. Your decision to bargain, steal, fight or run affects the scenario and the action and eventual outcome is rarely the same.

S2 EAMON Introductory Offer

You get the EAMON Master with the Beginner's Cave, The Orb of Polaris, Operation Crab Key, The Feast of Carroll, EAMON Utility 1 and the Dungeon Designer version 6.0. Includes volumes E1, E33, E44, E45, U1, D6. *A popular sampling of 6 EAMON volumes for only \$20.*

S3 Art & Graphic

Every Art & Graphic volume. Includes volumes 4 through 13, 93, 94. *12 volumes for only \$40.*

S4 Business & Finance

All of the very popular Business & Finance volumes. Includes: 18 through 25. *8 volumes for only \$28.*

S5 Games

Golf, hockey, ping-pong, poker, Hi lo, blackjack, cribbage, craps, chess, bowling, parachute, pinball, dragon maze, star trek, fizz bin, tank, keno, war lords, roulette, lunar lander and more. Includes volumes 36 through 57. *22 game-packed volumes for only \$75.*

S6 Utilities

Disk utilities, printer programs, assemblers, and disassemblers. It's all here. Includes volumes 74 through 87. *Get 14 Utility volumes for only \$48.*

S7 Tutor and Math Combo

From BASIC programming to multiple linear regression, you'll find what you need with these tutor and math volumes. Includes: 1, 2, 3, 59 through 63. *An 8 volume selection from Apple Tutor and Math & Statistics for only \$28.*

S8 Chemistry and Math Combo

A choice selection for the scientifically inclined. Includes one Chemistry & Biology and five Math & Statistics: volumes 26, 59 through 63. *All six volumes for only \$20.*

S9 Public Domain Software (PDS) Introductory Offer

Includes one volume from each category: Apple Tutor, Art & Graphic, Astronomy, Aviation, Business & Finance, Chemistry & Biology, Demonstration, Education & School, Electronic & Radio, Food, Game, Hello & Menu, Math & Stats, Music & Sound, Passion, Pastime & Other, Unknown, Utility, Apple Bank, and Library. *22 volumes for only \$75.*

There are over 175 volumes in the Computer Learning Center's Public Domain Library collection. All of these volumes will run on Apple II Plus computers and Apple-compatibles. Most will also run on the //e and //c. Each program in the collection has been donated to the public and has no copyrights attached. Therefore, each may be copied and distributed by anyone without regard for origin or ownership.

Public Domain Software is not commercial quality and is supplied as-is.

For more information on Public Domain Software from the Computer Learning Center (CLC), check the box on the order form to receive a copy of our NEW catalog.

Rush me the PDS items I have checked below. I understand that the volumes in each SPECIAL OFFERS package are packed on double-sided disks. (Offer good for a limited time only)

any of the articles published in Hardcore COMPUTIST detail the removal of copy protection schemes from commercial disks or contain information on copy protection and backup methods in general. We also print bit copy parameters, tips for adventure games, advanced playing techniques (APT's) for arcade game fanatics and any other information which may be of use to the serious Apple user.

Hardcore COMPUTIST also contains a center CORE section which focuses on information not directly related to copy-protection. Topics may include, but are not limited to, tutorials, hardware/software product reviews and application and utility programs.

What Is a Softkey Anyway? Softkey is a term which we coined to describe a procedure that removes, or at least circumvents, copy protection that may be present on a disk. Once a softkey procedure has been performed, the disk can usually be duplicated by the use of Apple's COPYA program (on the DOS 3.3 System Master Disk).

Commands and Controls: In any softkey procedure, the actual keystroke commands which a reader is required to perform are set apart from normal text (typed in bold and indented). An example is:

PR#6

Follow this with the RETURN key. The RETURN key must be pressed at the end of every such command unless otherwise specified.

Control characters and shifted characters are indicated in commands as small superscripts.

^{CTRL}P

To complete this command, you must first type the number 6, and then place one finger on the CTRL key and one finger on the P key. Shifted characters have a small SHIFT before them.

Requirements: Most of the programs and softkeys which appear in Hardcore COMPUTIST require one of the Apple II series of computers and at least one disk drive with DOS 3.3. Occasionally, some programs and procedures have special requirements: a sector editing program or a "nonautostart" F8 monitor ROM. The prerequisites for deprotection techniques or programs will always be listed at the beginning article under the "Requirements:" heading.

Software Recommendations: Although not absolutely necessary, the following categories of utilities are recommended for readers who wish to obtain the most benefit from our articles:

- 1) **Applesoft Program Editor** such as Global Program Line Editor (GPLE).
- 2) **Disk Editor** such as DiskEdit, ZAP from Bag of Tricks or Tricky Dick from The CIA.
- 3) **Disk Search Utility** such as The Inspector, The Tracer from The CIA or The CORE Disk Searcher.
- 4) **Assembler** such as the S-C Macro Assembler or Merlin/Big Mac.
- 5) **Bit Copy Program** such as COPY II+, Locksmith or The Essential Data Duplicator.
- 6) **Text Editor** capable of producing normal sequential text files such as Applewriter II, Magic Window II or Screenwriter II.

You will also find COPYA, FID and MUFFIN on the DOS 3.3 System Master Disk useful.

Hardware Recommendations: Many softkey procedures require that the user be able to enter the Apple's system monitor during the execution of a copy-protected program. Check the following list to see what you will need:

Apple II Plus / Apple IIe / Apple compatibles: 1) Place an Integer BASIC ROM card in one of the Apple's slots. 2) Use a non-maskable interrupt (NMI) card such as Replay or Wildcard.

Apple II Plus / Apple compatibles: 1) Install an F8 ROM with a modified RESET vector on the computer's motherboard. This method was detailed in Ernie Young's article, "Modified ROMS" (Hardcore COMPUTIST No. 6).

Apple IIe / Apple IIc: 1) Install a modified CD ROM on the computer's motherboard. Don Lancaster's company (Synergistics, Box 809-AP, Thatcher, AZ

85552) sells the instructions necessary to make this modification but access to an EPROM burner is also required. Making this modification to an Apple IIc will void its warranty, but gaining the ability to RESET into the monitor at will greatly enhances the capacity of the Apple owner to remove a disk's copy protection.

A 16K or larger RAM card, a printer, and a second disk drive are also recommended for Apple II or II+ owners.

Recommended Literature: The Apple II and II+ 's came bundled with an Apple Reference Manual, however this book is not included with the purchase of an Apple IIe. You'll find that this book is necessary reference material. A DOS 3.3 manual is also recommended.

Other helpful books include: *Beneath Apple DOS*, Don Worth and Peter Lechner, Quality Software, \$19.95, *Assembly Lines: The Book*, Roger Wagner, Softalk Books, \$19.95, and *What's Where In The Apple*, William Lubert, Micro Ink, \$24.95.

Keying in Applesoft Programs: BASIC programs are printed in Hardcore COMPUTIST in a format that is designed to minimize errors for readers who key in these programs. To understand this format, you must first understand the formatted LIST feature of Applesoft.

If you strike these keys:

10 HOME:REMCLEAR SCREEN

a program will be stored in the computer's memory. Strangely, this program will *not* have a LIST that is exactly as you typed it. Instead, the LIST will look like this:

10 HOME : REM CLEAR SCREEN

Programs don't usually LIST the same as they were keyed in because Applesoft inserts spaces into a program listing before and after every command word or mathematical operator. These spaces usually don't pose a problem except in line numbers which contain REM or DATA command words. The space inserted after these command words can be misleading. For example, if you want a program to have a list like this:

10 DATA 67,45,54,52

you would have to omit the space directly after the DATA command word. If you were to key in the space directly after the DATA command word, the LIST of this program would look like this:

10 DATA 67,45,54,52

This LIST is different from the LIST you wanted. The number of spaces you key after DATA and REM command words is very important.

All of this brings us to the Hardcore COMPUTIST LISTing format. In a BASIC LISTing, a space that *must* be keyed in is printed as a delta character (Δ). All other spaces were put in by Applesoft and it doesn't matter whether you key them in or not.

There is one exception: If you want your checksums (see "Computing Checksums" section) to match up, you must not key in any spaces after a DATA command word unless they are marked by delta characters.

Keying In Hexdumps: Machine language programs are printed in Hardcore COMPUTIST as both source code and hexdumps. Only one of these formats need be keyed in to get a machine language program. Hexdumps are the shortest and easiest format to type in. First, you must enter the monitor:

CALL -151

Now key in the hexdump exactly as it appears in the magazine ignoring the four digit checksum at the end of each line (a "\$" and four digits). If you type something incorrectly, a beep will alert you to retype that line.

When finished, return to BASIC with a:

E003G

Remember to BSAVE the program with the correct filename, address and length parameters as given in the article.

Keying In Source Code: The Source Code portion of a machine language program is provided only to better explain the program's operation. If you wish to key it in anyway, you will need an assembler. The S-C Assembler is used to generate all source code printed in Hardcore COMPUTIST. Without this assembler, you will have to translate pieces of the source code into something *your* assembler will understand. A table of S-C Assembler directives just for this purpose is printed on page 26 of this magazine. To complete the translation process, you need to understand the directives of your assembler and convert the directives used in the source code listing to directives similar to those used by your assembler.

Computing Checksums: Checksums are four digit hexadecimal numbers which verify whether or not you keyed in the program exactly as it was printed. There are two types of checksums: one created by the CHECKBIN program (for machine language programs) and the other created by the CHECKSOFT program (for BASIC programs). If the checksums these programs create on your computer match the checksums accompanying the article, then you keyed in the program correctly. If not, the program is incorrect at the line where the first checksum differs.

1) To compute CHECKSOFT checksums:

**LOAD filename
BRUN CHECKSOFT**

Get the checksums with

&

And correct the program where the checksums differ.

2) To compute CHECKBIN checksums:

**CALL -151
BLOAD filename**

Load the CHECKBIN program at an out of the way place and hook it up

BRUN CHECKBIN, A\$6000

Then type the starting address, a period and ending address of the file followed by a ^{CTRL}Y.

XXXX.XXXX^{CTRL}Y

And correct the lines at which checksums differ.

How-To's Of Hardcore

Welcome to Hardcore COMPUTIST, a publication devoted to the serious user of Apple II and Apple II compatible computers. Our magazine contains information you are not likely to find in any of the other major journals dedicated to the Apple market.

Our editorial policy is that we do NOT condone software piracy, but we do believe that honest users are entitled to backup commercial disks they have purchased. In addition to the security of a backup disk, the removal of copy protection gives the user the option of modifying application programs to meet his or her needs.

New readers are advised to read this page carefully to avoid making errors when following the softkeys or typing in the programs printed in this issue.

9 A Tutorial For: Disk Inspection And The Use of Super IOB

Confused about how to write a Super IOB controller? This article takes you step-by-step through the deprotection process and uses a generalized procedure to illustrate the creation of Super IOB controllers. You'll also discover how to use some other tools as disk inspection devices. *By Wes Felty.*

13 The Print Shop: A Softkey

This powerful utility program is finally opened up for inspection. Learn how a nibble count routine protects this high performance Broderbund program and why the original disk has two VTOC's. *By William Hinger & Albert Stoekten. Stocker*

16 The Graphic Grabber For The Print Shop

The Print Shop's Graphic Editor lacks some of the more sophisticated features of other similar programs (fill, brushes, etc.). Now, with the Graphic Grabber, you'll be able to snatch a picture created with *another* editor (such as Koalainter) and use it as a Print Shop graphic. *By Ray Darrah.*

CORE SECTION

20 The Lone Catalog Arranger v1.0

Part Two: The machine language program. Combine the program in this second installment of The Lone Catalog Arranger with the program which appeared in The Lone Catalog Arranger: Part One, HC No. 16. Together, these two programs provide a useful disk directory editor. Includes these commands: file order modification, renaming, deleting, and undeleting. *By Ray Darrah.*

24 BUGS!

25 Softkey For Crossword Magic

Create a completely copyable version of Crossword Magic with this boot code trace-type procedure. With a little finesse, you may even be able to put both sides of the original onto one side of a disk. *By Paul Selby.*

15 ADVENTURE TIPS

Input

Superpilot on a Corvus?

I've never seen so much information that I've been looking for in a single publication, ever. I think it would be a great idea if you included copy protection info for the MacIntosh as well. I don't own a Mac but, undoubtedly, there are some interesting protection methods used on its software.

By the way, does anyone know how to put Apple's SuperPilot onto a CORVUS hard disk or any other hard disk?

Victor Tan
Republic of Singapore

Put a Ronco in Your Apple

page 34
Going all the way back to Hardcore COMPUTIST No. 2, I have a few corrections to the program called "Three-D Wall Draw":

- 1) Line 10 should read GOSUB 490
- 2) Lines 220 through 240 should read THEN 690...710...850, respectively
- 3) Add line 1055...POKE -16386,0...and GOSUB 1055...from lines 220 through 250 as well as lines 270, 290, 310 & 330
- 4) Line 250 may be deleted altogether since the Wall only "draws" while the key is depressed (watch out if you have a 'type-ahead' buffer).

Now, can anyone tell me how to eliminate the pivoting effect at the edge of the screen window?

Here is a hardware tip: Technically, the Apple II with its standard power supply is in virtual overload condition with a minimum of boards. Say, a RAM Card, a Drive Controller card and one other, possibly a RAM-DISK Board. You can fry eggs on the power supply as well.

The add-on fan that can be purchased for \$40.00 to \$50.00 is aesthetically pleasing and moves approximately 20 cfm of air through your Apple. The Ronco room air recycler that I purchased for \$7.95 moves 40 to 50 cfm through my Apple. With a full complement of boards, including a Z80 and 256K of RAM-DISK, my power supply is cold to the touch after being left on all day, even during summer temperatures of 90+.

Take a piece of dense sponge foam 10x7x4" and with a magic marker draw a 5" circle on the largest surface about 4" from one end. Using a sharp knife, cut the circle out completely. Now make an L-

shape by reducing the 4" dimension by 2/3 the original length and across the 5" hole. Next, remove material on the inside surface of the L but leave the edges intact. Finally, remove the sloping filter holder from atop the fan and discard it. Invert the fan and jam it into the hole. Place the entire assembly on top of your Apple so that it covers the louvers on the most convenient side (the left). You should not experience any more overheating problems. (I have installed an extra heavy-duty power supply in my Apple.)

On another topic: I find it very sinister that LS 5.0 copies itself without much trouble except that the resulting copy doesn't work. Even applying hints gained from Hardcore COMPUTIST has not helped. Also, the original LS 5.0 will make closer working copies of protected programs than will a liberated copy.

I have WAY-OUT by Sirius Software and my original LS 5.0 makes a copy (it goes through the entire boot process before the program detects that it is a clone and reboots). My copy of LS 5.0 won't make a duplicate that even comes close to booting. (By the way, can anyone tell me how to decipher the maze loading table in WAY-OUT located in the loader at 988F to 98AB, inclusive?)

I've requested info from Alpha Logic Systems regarding LPL (Locksmith Programming Language) and also info on how to fix the bug in Locksmith's Editor. Obviously, the author of the LS 5.0 review did not try out the program or else he's on the ALS payroll.

Problem 1) The Text Editor gobbles up characters on the following line when you are editing a line of an LPL file.

Problem 2) There is no glossary of programming statements but there are plenty of hints if you review the Newsletter with the various LPL files for backing-up specific programs.

Problem 3) There is a lack of program feedback. If an LPL file is changed, LS does not inform you of what is happening or even that anything has been changed.

Your magazine is ideal for us Apple Hackers. Please keep it up.

Norman F. Hogarth
Lilith, CA

* see No. 20,
page 4 - WAYOUT
copy technique

Mr. Hogarth: Thank you very much for your input and tips, especially the one about the inexpensive fan. We have heard that Veg-O-Matics work quite admirably

for notching out the back sides of disks (just kidding, folks).

We've forwarded your complaints about Locksmith 5.0 to AL Business Systems.

APT for Advanced Lode Runner

recently wrote your staff with a question concerning an article in the Best of Hardcore Computing.

I was pleasantly surprised when I received a reply in less than a week. The staff of Hardcore COMPUTIST is to be commended for producing a first class magazine. Keep up the good work!

A friend of mine discovered a trick which relieves some of the frustration of trying to play Advanced Lode Runner. Advanced Lode Runner does not have all the special features of the regular Lode Runner such as starting at any level, adding more men or skipping levels. Initialize a new data disk using the original Lode Runner, use a good nibble copier such as EDD III to copy tracks 3 through 6 from Advanced Lode Runner to the newly initialized disk, and the original Lode Runner thinks the new data disk contains levels created by you. You can now play all levels of Advanced Lode Runner using the special features available in the original Lode Runner by ending a game with CTRL-R. Press CTRL-E to enter edit, press P to select level, place the new data disk in the disk drive and press RETURN.

Thanks again for a great magazine and may you continue to prosper.

Warren W. Power
Davenport IA

Sensible Speller on the //c

public thanks to your publication for a very worthwhile source of information on the ins and outs of disk protection. Keep up the fine work.

Your readers should know that the diskette offered by Marco Hunter in Hardcore COMPUTIST No. 9 is loaded with valuable material in its collection of programs and text files.

The //c owners should know some good news about the DOS 3.3 version of Sensible Speller, Rev. 4.1b, which will not boot on these machines. Once you deprotect the revision (and I assume any of the others), using Lamont Cranston's softkey in Issue No. 10, the program boots very rapidly and

Input cont...

runs on the //c. His procedure does not require a card and can be completed on either a //e or //c. Follow his directions along with the entry points specified in **Doni G. Grande's article in Issue No. 11** and you have a program that will work on either your //e or //c...as is the case with me.

Rod Sobieski
Emporia KS

StickyBear Feedback

would like to add to Mr. Jerry Caldwell's softkey on the Stickybear software series (featured in Issue No. 15).

In his article, Mr. Caldwell uses Stickybear BOP to demonstrate his softkey. It has been verified that Stickybear reads the protected sector into the buffer locations \$300. He then boots up the original disk, enters the monitor and saves \$300 in a safe place where it will not be overwritten when booting up a normal DOS 3.3 disk. He moved \$300 to \$9000-\$90FF, booted up the DOS 3.3 disk and BSAVED PROTECTED SECTOR, A\$9000,L\$100. Writing this protected sector back to the backup you've made can be a little shaky for beginners. Here's where the little adjustment comes in:

Instead of moving \$300-\$3FF to \$9000, move it to \$6000 (it's just a nice number to tinker with).

6000 < 300.3FFM C600G

Now boot a DOS 3.3 diskette without a HELLO program (remember that you copied \$300-\$3FF into \$6000-\$60FF). Instead of BSAVEing the protected sector, let's just write it directly to the backup disk that you made (since it's already in memory). This short write routine will do the job:

CALL-151

```
300:20 E3 03 ;THIS SETS UP DOS' RWTS
          ROUTINE
303:4C D9 03
87EB:00 02 0F ;SET TRACK AND SECTOR
              (TRACK $02 AND SECTOR $0F)
87F0:00 60 ;BUFFER (STORAGE) IN
              LO-HIGH ORDER ($6000)
87F2: 00 00 02 ;THE '02' TELLS RWTS TO
              WRITE A TRACK & SECTOR
```

Now you're ready to write! Insert the backup you've made of Stickybear and from the monitor type:

300G

You now have a perfectly COPYABLE Stickybear BOP diskette.

I used this technique of writing a sector because when you BSAVE the protected sector, it creates a third sector which makes it impossible to write into a single sector without a sector editor. The third sector is due to a binary files address and length information. This technique writes a sector to disk as long as you specify the buffer address and the track and sector, of course.

Another tip: If you have an Apple][Plus and a language card and don't know how to enter the monitor, you can simulate an old 'F8' ROM by programming your language card. For slot 0:

CALL -151

```
C081 N C081 ;WRITE ENABLE RAM CARD
D000<D000.FFFF ;COPY ALL ROMS INTO THE
              CARD
FFFC:59 FF ;SET TO JUMP INTO THE
              MONITOR UPON RESET
C083 N C083 ;WRITE PROTECT RAM CARD
```

This works perfectly on the Stickybear series because it doesn't check or turn off the language card. If, however, a program turns off or 'sees' the language card, try this: Move the card to slot 1 or 2 and the following number will change accordingly:

```
For Slot 1: C081 ->C091
             C083 ->C093
For Slot 2: C081 ->C0A1
             C083 ->C0A3
```

NOTE: This method will not work all the time.

Hardcore COMPUTIST is already my favorite magazine (I just received my first issue). Keep up the great work and don't die out like Softalk did!

Randy Ramirez
Los Angeles CA

Educational Softkeys Please

I am writing to let you know how much I enjoy your magazine. It is very informative and useful. I have used a number of your softkeys to backup my software. However, there is one field that needs more attention: educational software. I'm a teacher and we need to be able to backup our software before little fingers sticky with peanut butter and jelly get ahold of it. The one that I need a softkey for most desperately is Broderbund's, "Print Shop".

Also, you mention using an Integer Basic ROM to RESET into the monitor. We have an old Apple][Plus with an Integer Basic Card (red switch on the back) installed. Is this the same card? If it is, will it work in an Apple //e? If so, how? If not, how can I interrupt into the monitor without a Wildcard?

George Cox
Beaufort Middle School
Beaufort, NC

Mr. Cox: We agree that it is very important for teachers to be able to backup the software they use in the classroom. We always try to include educational softkeys in Hardcore COMPUTIST and we encourage our readers to submit softkeys for educational software.

The Integer card that you own will allow you to RESET into the monitor. When you want to perform the RESET, just flip the switch on the card to the up position before hitting the RESET key. This card is compatible with the Apple //e's.

Needs Ultima II Help

elp! A previously published Ultima II article was mentioned in Issue No. 11, but I don't have any of the original magazines. Can anyone tell me how to access Lord British' monster shape tables?

I would like to voice my opinion on bringing other Apples into this magazine. NO WAY! All too many computer magazines contain information on other machines which is of no interest to me, since I can't perform the techniques on my Apple //e.

Also, could you republish a method to RESET into the monitor via "Moving Your RAM Card to Slot 1" from Issue No. 9? My subscription did not include that issue, and I would like to be able to put the "Locksmith 5.0 Fast Copy" into a BRUNable file.

Rob Klingsten
Howell, MI

Mr. Klingsten: The original Ultima II article appeared in HC No. 4. It is still available as a back issue.

To move your language card to a slot other than zero, see the above informative letter from Randy Ramirez.

Readers' Softkey & Copy Exchange

Toppling The Standing Stones

By Steven Zupp

Standing Stones
Electronic Arts
2755 Campus Drive
San Mateo, CA 94403
(415) 571-7171
\$40.00

Requirements:
48K Apple with one disk drive
COPYA
Sector editing program
One blank disk

The protection for Standing Stones does not use any defenses against normal disk copiers at all. Instead it uses a tricky half-track check.

This under normal conditions would be just fine. We could pull out our trusty nibble copier and copy it right off. Unfortunately, Standing Stones cleverly checks not only the half-track of 21.5, but also checks track 21 and 22. Since any attempt to copy the half-track would also destroy 21 and 22, and any attempt to copy 21 or 22 would destroy 21.5, we can throw our nibble copier out the window.

Fortunately, there's a remote possibility that with a nibble copier that can do quarter tracks, you can copy just the right combination of tracks to do it.

Track 21 and 22 are not used for any purpose except the copy protection which we will later unhook. Track 22 is not COPYAable, but this doesn't matter.

Start up COPYA and copy from Standing Stones to the blank disk. After a while it should beep and say UNABLE TO READ. What has happened is that it has reached track 22. Ignore the message and remove the disks.

Now boot up your favorite sector editor. Insert the copy disk and read in track \$11, sector \$4. Change bytes \$44 - \$49 (20 D9 03 20 00 0D) all to EA. Now write it back to the disk. It should now boot perfectly and you can also make error free copies of this disk with any copier.

Looks like EOA has joined Sierra On-Line in leaving nice little messages. If necessary set your sector editor in the ASCII or character mode and read track \$11, sector \$2.

Deprotecting Beer Run By Clay Harrell

Beer Run
Sirius Software, Inc.
10364 Rockingham
Sacramento, CA 95827
(916) 366-1195
\$29.95

Requirements:
48K Apple II or II Plus
A way to Reset into the monitor
A 48K slave disk with no HELLO program
Beer Run from Sirius Software

Beer Run is a challenging game written by the same fellow that wrote the classic Apple game, Sneakers. Beer Run is a ladder and climb game that is very difficult to play, and challenges you to find the "Artesians".

Sirius has made Beer Run fairly difficult to backup by conventional means. After loading Beer Run and resetting into the monitor, a quick cruise down memory lane reveals that Beer Run is a large game, occupying most of the 48K of motherboard memory.

The large size of the game is a result of the large size of the shapes in the demos. These "shape tables" use much of memory yet are unnecessary for the actual game. If we neglect the demo, we can put Beer Run into an ordinary binary DOS file.

Even though Beer Run uses most of memory, we can still save it to a DOS file because "page switching" is used for its graphics. This technique of graphics involves writing on one of the hi-res pages, while showing the other. The newly drawn page is then shown and the other page is updated and drawn on. This process of "page switching" continues very quickly to provide us with very smooth and flicker-free graphics. Of course, hi-res pages one and two are used (\$2000 to \$5FFF); therefore, there can be no code there when the game starts. Memory from \$400 to \$1FFF and \$6000 to \$BEFF are used for the code and shape tables. Consequently, we must save these portions of memory.

The author uses a conventional starting address of \$800. To discourage the Replay and Wildcard owners, Sirius has put in some disk access which checks for your original disk. This routine is easily defeated, but also deletes the demo at the

same time.

We know what to do now, and all that's left is to put it in a binary BRUNable file. We must clear the way for a 48K slave disk boot which will wipe out \$800 to \$8FF and \$9600 to \$BFFF.

Step-By-Step

1) Boot the game and, when the prompt "Paddles (P) or Keyboard (K)" appears, reset into the monitor.

2) Remove the disk access during the game

```
BB00:4C 00 08
```

3) Compact the Beer Run Code and move page eight out of the way for a boot

```
2000 < 8000.BEFFM  
8000 < 800.900M
```

4) Boot your 48K slave disk with no HELLO program.

5) After DOS is loaded, move \$8000 to \$80FF back down to \$800

```
CALL -151  
800 < 8000.80FFM
```

We now need a way to move memory from \$2000 to \$5FFF back up to \$8000 to \$BFFF after the file is loaded by DOS. We can't ask DOS to do this since DOS lives from \$9D00 to \$BFFF. If we did, DOS would be overwriting itself. Therefore, we must write a "memory move" routine.

The idea behind a memory move is simple: load a file into memory between \$800 and \$9600 and then jump to a machine language routine that copies memory from lower memory locations into higher locations.

When the routine is done, Beer Run will be back where it belongs and we can jump to the starting location at \$800. The routine will look like this (take a look even if you don't know ASSEMBLY language):

```
5F00: LDX #500 ;X = 0  
5F02: LDA $2000,X ;A = no's at ($2000+X)  
5F05: STA $8000,X ;loc ($8000+X) = A  
5F08: INX ;X = X + 1  
5F09: BNE $5F02 ;if not 0, goto $5F02  
5F0B: INC $5F04 ;incr pg to load from  
5F0E: INC $5F07 ;incr pg to store to  
5F11: LDA $5F04 ;A = pg to load from  
5F14: CMP #5F ;compare to $5F  
5F16: BNE $5F00 ;if not =, goto $5F00
```

6) A good place to put this routine would be at \$5F00 since this page of memory is unused by Beer Run. Type the following:

```
5F00: A2 00 BD 00 20 9D 00 80
5F08: E8 D0 F7 EE 04 5F EE 07
5F10: 5F AD 04 5F C9 5F D0 E8
```

7) Now let's make the Beer Run code JuMP to this routine before starting up

```
7FD:4C 00 5F
```

Now we must determine how to save the code that is used across text page one. Notice that when you hit reset, the text screen has "garbage" on it. This code is not necessary, but Beer Run checks for it and, if it is not there, the game will not run. This is easily solved by moving (or filling) the text page with \$60's which represents a Return From Subroutine in machine language. Whenever Beer Run tries to jump to a subroutine on the text page, it will immediately return back to the calling routine. We may add this short routine to our memory move. The code looks like this:

```
5F18: LDX #500 ;X = 0
5F1A: LDA #560 ;A = $60
5F1C: STA $0400,X ;put A at ($400 + X)
5F1F: INX ;X = X + 1
5F20: BNE 5F1A ;if not 0, goto 5F1A
5F22: INC 5F1E ;incr pg to store to
5F25: LDA 5F1E ;A = pg to store to
5F28: CMP #508 ;compare to 508
5F2A: BNE 5F1A ;if not = goto 5F18
5F2C: JMP $0800 ;start Beer Run
```

8) Enter the following hex code which is the same as the code above

```
5F18: A2 00 A9 60 9D 00 04 E8
5F20: D0 F8 EE 1E 5F AD 1E 5F
5F28: C9 08 D0 EE 4C 00 08
```

9) Now we may save our file to disk by typing

```
BSAVE BEER RUN,A$7FD,LS7803
```

Beer Run is now deprotected and BRUN-able from DOS 3.3.

IMPORTANT!

Please note that the Post Office does not inform our subscription department when you file a change of address. You MUST send a change of address to Hardcore COMPUTIST on postal form 3576. Issues missed due to non-receipt of change of address can be purchased at the current back issue price.

The Skyfox Softkey By Marshall Strouse

Skyfox
Electronic Arts
2755 Campus Drive
San Mateo, CA 94403
(415) 571-7171
\$40.00

Requirements:
Apple or compatible with 64K
One disk drive
Super IOB
A blank disk

The program Skyfox from Electronic Arts is one of the best programs I've ever seen because of its unique smooth motion graphics.

The protection used on SkyFox is equally good. It is essentially the same one that is used on many of Electronic Arts' newer releases such as One-On-One, Archon, Seven Cities of Gold and others so you may be able to use this procedure on other E.A. programs.

The disk can be copied with any good bit copier without generating any error codes, but due to a difficult-to-reproduce nibble pattern on track 6, such a copy will usually not work. As such, I was forced to boot code trace the disk.

The boot starts in the disk controller in one of your slots. Because the first byte of sector zero, on track zero is a \$06 (instead of the usual \$01), the controller ROM loads just about all of track zero into \$800 up to \$DFF. Next, this first boot loads tracks 1 and 2 into \$A000 and \$B000, respectively. This second code has an entry point of \$A806.

This second code first checks for a language card and, if there is one, it continues executing. If there is no language card present, it turns on the text page and just hangs. If there is a 16K card, then tracks 3, 4, 7 and 8 are loaded into memory locations \$4000, \$5000, \$6000, and \$8000, respectively.

And Now, The Fun!

This code now does a checksum on its nibble count routine to make sure that it hasn't been changed. If the nibble read routine is unchanged, it continues on. If changed, the computer hangs again.

If the checksum of the nibble count is O.K., it is executed. If the correct nibbles are not found on track six, it again hangs!

If the nibbles on track 6 are correct, it then does a RAM de-encryption to make it runnable machine code. By the way, all memory loaded on all E.A. games is encrypted.

We're not finished yet. If you were to pick a tank or low flight mission, it does a check on the disk again, which fails if the original isn't in the drive. In a condensed form, we must remove the protection by disabling the two nibble counts.

The Procedure

We will deprotect the disk by using a modified version of the Electronic Arts controller that was printed in Hardcore COMPUTIST No. 13. The controller (at the end of this article) has been modified to skip tracks 5, and 6 and to perform some sector edits. Because of the number of sector edits necessary, I did not use the standard Super IOB sector edit routine, but instead used a routine at lines 1210-1220 to POKE the necessary monitor commands into the Apple's input buffer. This routine is convenient for a Super controller that has to make numerous sector edits during the copy process. You do, however, have to calculate the proper locations in Super IOB's track/sector buffer where the changes are to be made.

1) Get out your Super IOB and use the controller at the end of this article to deprotect SkyFox. You will notice a pause of several seconds after the first range of tracks has been read. This pause is normal and occurs while the monitor commands are being POKEd into the input buffer.
2) That's all, folks.

What Happened?

First of all, track 2, sector 0 was modified in this manner:

a) Byte \$AA was changed from a \$A0 to a \$60.

b) A short intercept routine was placed starting at Byte \$D5. This code will end up at \$BFD5 in memory.

```
BFD5- 68 PLA
BFD6- A9 05 LDA #505
BFD8- 20 00 BC JSR $BC00
BFD8- A2 06 LDX #506
BFDD- BD F9 BF LDA $BFF9,X
BFE0- 9D E5 A2 STA $A2E5,X
BFE3- CA DEX
BFE4- 10 F7 BPL $BFD0
```

Exchange cont...

```

BFE6- A9 4D LDA #S4D
BFEB- A2 FF LDX #SFF
BFEA- A0 0E LDY #S0E
BFEC- 60 RTS
BFED- EA NOP
BFEE- 48 PHA
BFEF- A5 43 LDA $43
BFF1- C9 A0 CMP #S40
BFF3- F0 E0 BEQ $BFD5
BFF5- 48 PLA
BFF6- 6C 00 42 JMP ($0042)
BFF9- 00 52 AD 4D A6 A1 4D
    
```

An edit must now be done to make SkyFox jump to this routine. The place to put the jump to our routine was found on track 1, sector 5.

See the short listing below of the code preceding the location where our jump must be placed. With a little luck, you may find it on other E.A. programs as well.

```

SAAA3- 20 77 AA JSR SAA77
SAAA6- 98 TYA
SAAA7- 48 PHA
SAAA8- 65 48 LDA $48
SAAA9- 20 B7 AA JSR SAAB7
SAAA0- 85 48 STA $48
SAAAF- 68 PLA
SAAB0- A8 TAY
SAAB1- 4C 3A AA JMP SAA3A
SAAB4- 20 77 AA JSR SAA77
SAAB7- 6C 42 00 JMP ($0042)
    
```

It is the indirect JMP at location SAAB7 we wish to change. The Super IOB controller changes bytes \$B7-\$B9 of track 1, sector 5 from \$6C, \$42, \$00 to \$4C, \$EE, \$BF.

Congratulations

You are all done and now the proud owner of an unprotected copy of SkyFox. As I finished up this article, I discovered that track 6 has a self-modifying nibble count, which means that it changes every time you read it.

Softkey For Random House Disks By Mike Stafford

**Peanuts Maze Marathon
Random House Inc.
400 Hahn Rd.
Westminster MD 21157**

Requirements:
Apple II Plus or equivalent
A way to RESET into the monitor
One blank disk
Super IOB & Swap Controller (HC No. 14)

The Peanuts educational series by Random House offers an exceptional value for the money. Excellent quality programs

featuring beautiful graphics fill the double-sided disks I have seen. In addition to Maze Marathon, I have also softkeyed Charlie Brown's ABC's using the same procedure, so it's probably safe to assume that most of the disks in the Peanuts series can be deprotected using the method described below.

Among other things, these disks employ altered address and data headers as a form of copy protection. Fortunately, we really don't have to get too deeply into this, as you can use the standard Super IOB program and the normal Swap Controller to accomplish this softkey. In fact, I the same RWTS remained installed for both disks. Here's the step-by-step method:

1) First boot up DOS (preferably a fast DOS, such as Diversi-DOS), enter the monitor and apply a patch that will permit the use of a binary greeting program

**CALL-151
9E42:34**

2) Initialize a blank disk

INIT STEX

3) Boot the Random House disk. As soon as it stops loading, RESET into the monitor by your favorite method.

4) Move the RWTS to a safe location

1900 < B800.BFFM

5) Insert your slave disk and boot it

C600G

6) Save the RWTS

BSAVE RWTS,AS1900,LS800

7) Install the Swap Controller in Super IOB and start the copy process by typing

RUN

8) Repeat Steps 1, 2 and 7 to make a copy of the back side of Peanuts Maze Marathon.

These disks can now be COPY'd and cataloged. If you used a fast DOS, the loading time of the copies will have been reduced by two-thirds.

Want To Order Back Issues?

See pg. 30

A Tutorial For:

Disk Inspection And The Use of Super IOB

Requirements:

Super IOB v1.2
Disk Utility programs such as:
Locksmith 5.0
EDD
Bag Of Tricks
CIA

A quest for knowledge

 Super IOB is great for deprotecting programs and for opening them up to investigation and/or modification. With this versatile program, deprotecting is usually as easy as typing in the IOB Controller and RUNNING Super IOB. Using Super IOB version 1.2, you don't even have to do any sector edits. Fortunately, all of the softkeys which have appeared in Hardcore COMPUTIST in past issues which use the modified COPYA and sector edit method can be modified to use Super IOB v1.2. However, creating your own controllers may pose a problem. Hardcore COMPUTIST frequently prints Super IOB Controllers, but often the author of the controller does not provide a lot of comment on how the controller was created. It's very easy to use a Super IOB Controller once you have one, but creating your own isn't so easy. To do so, you must determine precisely what protection scheme(s) are being used.

In this article, I will try to explain how Super IOB controllers are created. I will also touch on software "snooping" with tools like Locksmith 5.0, EDD, Bag of Tricks, CIA, and Super IOB.

The First Step

When investigating a disk, be very alert to everything you see and hear. Watch the screen while the disk is booting. If a prompt appears during the boot, then a reasonably normal DOS is probably in use. In this case, a RESET into the monitor sometimes allows the use of the modified DOS's CATALOG, LOAD and SAVE commands. Even if the text of the DOS commands has been changed, you can often view the disk's directory by calling the CATALOG routine directly with a CALL 42356 (A56EG from the monitor).

Be sure to listen carefully while a normal disk is booting. You should hear the gentle "woosh" sound at somewhat regular intervals as the disk drive read/write head moves to successive tracks. As you become familiar with this sound you will begin to distinguish this from the sound of a protected disk booting. I always compare the boot sound of my protected disks with that of

By Wes Felty

(No 114, page 10)

normal disks. If they sound similar (even if no prompt appears on the screen), there is a good chance that a reasonably normal DOS is being used.

On some disks, you may hear noises that do not resemble the sounds produced by the boot of a normal disk at all. The sound that Essential Data Duplicator makes when it boots has been compared to an army of tapdancing cockroaches. This boot sound stands in marked contrast to that of a DOS 3.3 disk. Similarly, with Zardax you hear a suspiciously quick "woosha, woosha, woosha" sound as the drive head pops back and forth between tracks 4.5 and 5.5 looking for the copy protection information. And during the Skyfox boot, there is a fast "click, click, click," sound as the drive reads a small

amount of information from eight to ten adjacent half tracks.

Strange boot sounds can tell you that even a super bit copier with extensive parameter settings will probably not work for certain tracks.

See The Tracks

If you take your disk investigation seriously, you'll want to **mark your disk drive cam** as outlined in **Hardcore COMPUTIST No. 5. WARNING!** Be careful when following this procedure! You can knock your drive head out of alignment doing this and you'll definitely invalidate any warranties still in effect.

Who's What is Where

The next thing to determine is how many tracks need copying. Locksmith 5.0 and EDD both have good options for finding this information. Using either of them, it is easy to tell that Zaxxon has information only on tracks \$00-\$16. Next, you need to find out what kind of sector modifications on the nibble level have been made. Most bit copy programs such as Locksmith, Nibbles Away, and Copy II+ will aid you with this, but Bag of Tricks and CIA are my favorites.

Bag Of Tricks

When Bag Of Tricks works, it does all of the hard work for you. Therefore, I usually try it first. It will provide you with the address and data prologues, epilogues, and checksums for each sector as well as a raw nibble dump for each track. If any of the information is nonstandard, it is printed in inverse. Unfortunately, Bag of Tricks doesn't always work if the sectors have been too severely altered.

Confidential Information Advisors (CIA)

Up front, CIA gives you less information than Bag of Tricks but it does give a better indication of whether your interpretations are correct or not. When first beginning my investigation of a protected disk, I load Tricky Dick with the Linguist (option 2) into my machine. Next, I try to read several sectors with Tricky Dick. Track 0, sector 0 can usually be read with no changes since your computer needs to be able to read it in order to start loading DOS. You may even be able to read all of the DOS tracks (tracks 0-2). If you can read every sector of every track, then the disk may be copied with COPYA or just about any other normal whole disk copier. Unfortunately, this is seldom the case. More often you will get a drive error on at least one sector of one track. At this point you have to do manually what Bag of Tricks does for you automatically.

Assuming that the disk uses a somewhat normal sectoring structure, you must figure out how each sector has been corrupted. Enter the Linguist module, read a track such as \$11, and look for the large groups of sync bytes. Usually they are FF's. If you do not see a large grouping of them, look instead for any other bunch of the same numbers (FE's, FD's, etc.).

Directly following the sync bytes you should find the D5 AA 96 address headers, eight address field bytes, DE AA address trailers, more sync bytes, D5 AA AD data headers, 342 bytes of encoded data and the DE AA data trailers. If all of these are correct, you might try another sector. If every sector seems to be correct, then the address field checksum or data field checksum is probably altered. Don't forget that by positioning the Linguist's cursor over the byte immediately following the address

header (D5 AA 96), that it will display what track and sector the nibbles belong to.

Testing Your Findings

When you think you know what the changes are, return to Tricky Dick and use CTRL-S to change the headers and trailers to what you found. To ignore the address field checksum, change the first "Y" to an "N" and to ignore the data field checksum, change the second "Y" to an "N". Now, here is where Tricky Dick pays for itself. You can try to read the sectors now with the modifications you just made and see if your interpretations are correct. If you are correct, then you know what changes must be made to the standard Super IOB Controller. If you can't read the disk's sectors by changing the address and data headers and trailers and ignoring the checksums, then you might not be able to use Super IOB to copy the disk.

Even if Bag of Tricks worked and showed you what changes were made to the sector markers, you should use CIA also, if you have it. Change the markers and see if Tricky Dick can now read the disk sectors. This will confirm that the Super IOB controller will work. You can also use Tricky Dick in conjunction with the Tracer to verify that the entire disk was written in the format that you found with the Linguist.

If you don't have Bag of Tricks and/or CIA, you can still use any bit copy program nibble editor to search a raw nibble dump and look for the changes in the sector markers mentioned above. Those two programs just make the job much easier to confirm the changes.

"Hardcore COMPUTIST gave an involved softkey for this program (Zaxxon) in Issue No. 7 which showed how to locate the copy protection using boot code tracing...Instead, I can show you how to create a Super IOB controller to copy and edit Zaxxon all in one simple step."

An Actual Example

Let's look at Zaxxon. A softkey for this program appeared in Issue No. 7 and, although it showed how to locate the copy protection using boot code tracing, it lacked an explanation of how the necessary sector edits were determined. Instead, I can show you how to create a Super IOB Controller to copy and edit Zaxxon all in one simple step. I must admit though, that Clay Harrell's article on "Deprotecting Zaxxon" was one of the best articles published by Hardcore COMPUTIST. Because it was carefully written and detailed how the

protection on Zaxxon was found, I was able to use the principles shown to fix my own copy of Zaxxon even though it was not one of those listed in the sector edit tables. In using Clay's article here, the most difficult and time consuming portion of the deprotection has already been accomplished. In fact, the normal softkey published in Hardcore COMPUTIST is, without doubt, the result of hours of hard work. It may not look like much when you see one or two simple looking sector edits for a softkey procedure (like with Locksmith 5.0 or PFS). But those simple looking changes are arrived at only after hours of investigation.

Back To Zaxxon

Using Locksmith 5.0's Quickscan routine or EDD's option 3 to examine the original Zaxxon disk, it was obvious that data is stored only on tracks \$00-\$16. EDD indicated that Zaxxon might have some information stored on the quarter or half tracks of \$10-\$13. I then watched my marked disk drive cam as I played Zaxxon. During the boot, the disk drive read tracks 0, 4, 11, 15, 14, 13, 12, 11, F, E, D, B, C, A, 9, and 8 before reaching the main menu. This told me that the information was only on the whole tracks and that the program most likely didn't use a Catalog structure but instead loaded information directly off of the disk. If it had a CATALOG, then it might have been found be on track 4.

Next, using Bag of Tricks' Trax program, I found that track 0 couldn't be analyzed and that the rest of the tracks had their address epilogues changed from "DE AA" to "CC AA". All of the other marks and checksums seemed to be normal. CIA confirmed that this was the main change. All of the tracks with information, even track 0, read properly. Using this information, I was then able to create a Super IOB Controller for Zaxxon. To create the controller, you will need to copy tracks \$00-\$16, 00-22 decimal, changing the address epilogue to "CC AA".

Unfortunately, the copy that results from the use of just this information will not work. A nibble counter in the program will prevent a copy like this one from running. But, you will at least have a COPYABLE working disk to try making changes on. This is where Clay Harrell's article comes in. He gave the sector edits for three different versions of Zaxxon and I have listed the edits for my version below. Decimal values are shown in parenthesis. These are needed for the DATA statements of a Super IOB controller.

Zaxxon Sector Edits

Trk	Sect	Byte	From	To
\$00	\$07	\$1F (31)	\$A9	\$4C (76)
\$00	\$07	\$20 (32)	\$00	\$C0 (192)
\$00	\$07	\$21 (33)	\$85	\$08 (8)
\$00	\$04	\$4F (79)	\$CC	\$DE (277)
\$00	\$04	\$50 (80)	\$D0	\$EA (234)
\$00	\$04	\$51 (81)	\$AE	\$EA (234)

A Super IOB Revolution

The Super IOB program is essentially an RWTS controller program with a number of subroutines to allow modifications to the standard sector structure. The trick to writing new controllers is in knowing where in the standard controller to call the other subroutines.

Presented below is what I call the SUPER controller. It is the standard controller with a whole bunch of lines inserted between the usual standard controller lines. These extra lines call various subroutines and are well documented. To activate one of these lines, you must remove the REM from the beginning of the statement. The documentation for each line is listed directly after the line and is printed here in lowercase for increased readability. Because of the structure of the standard controller, modifications to the reading of the disk are made in lines 1021 through 1028 and modifications to the writing of a disk are made in lines 1061 through 1069.

A Change Of Address

To change address or data headers or trailers with the Super controller, you must do four things. First of all, you must put the modified values in DATA statements at the end of the controller; line 5000 is a good place to start your data. Secondly, you must activate the RESTORE command of line 1021 by removing the REM just before it. This avoids an ?OUT OF DATA ERROR and ensures that the modified headers or trailers are read at the beginning of each read cycle. Next, you must activate the appropriate GOSUB statement(s) in lines 1022-1024. Note that if more than one mark is changed, the DATA at the end of the controller must appear in the same order as the GOSUBs that read them. For example, if you change the ending marks with line 1024, then you must include both pairs of end marks with the address marks coming first in the DATA statement. Finally, you must activate the GOSUB of line 1065 to normalize all of the address and data marks to be written to the copy disk.

There are really three ending marks on each field, but DOS ignores the third mark. Super IOB does, too. DO NOT try to include the third one. If you do, the controller will not work.

Giving A Checksum The Cold Shoulder

To ignore the address field checksum, activate line 1025. The activation of line 1026 will invoke a data field checksum change. The normal value is zero and the new value should be the next data element. If either of these routines are activated, then you must activate line 1065 so that the data read from the protected disk will be written normally.

I have brought back the "Ignore checksums and end marks" routine that was

removed in the creation of Super IOB v1.2. If you wish the checksums and end marks to be ignored, activate both line 1028 and line 1069.

Sector Editing

Sector edits will be performed if line 1067 is activated. Sector edits also require a DATA statement at the end of the controller. Be sure to have all other data appear before the sector edit data. Also, remember to activate the RESTORE of line 1021 if you use any sector edits.

Sector editing with version 1.2 of Super IOB is much easier to do than with the older version but first you must specify how many sector edits will be performed. This is accomplished through a DATA statement like this:

5010 DATA 2 CHANGES

The next data elements must then contain the decimal values of the track, sector, byte and new value (in that order) for each edit.

Modifying the Super Controller For Zaxxon

All of the routines to create a controller for Zaxxon already exist in the Super controller. All that is necessary for us to do is to activate the proper line numbers. Basically, the Zaxxon controller has to do three things:

- 1) Copy tracks \$00-\$16 (0-22)
- 2) During the read cycle, change the address epilogue bytes to "CC AA" or ignore the end marks
- 3) Perform the necessary sector edits

I tried using lines 1024 and 1065 to change the end marks, with "DATA 204, 170, 222, 170" for the end marks "CC, AA, DE, AA", and found that my controller didn't work. Therefore, I decided to use the "Ignore checksums and end marks" routine, lines 1028 and 1069, instead. This subroutine was dropped when Super IOB was updated to Version 1.2, but I still find it very useful.

To copy only tracks \$00 through \$16, I had to change the "LT = 35" in line 1010 to read "LT = 23". Ignoring checksums and end marks is accomplished by removing the REM at the start of lines 1028 and 1069.

The resulting Super IOB Controller can now read the original Zaxxon disk, write the program back to a new disk in a deprotected form, and make the sector edits, all in one program. With all of the deactivated lines removed, the resulting controller would look like this:

Zaxxon Controller

```
1000 REM ZAXXON CONTROLLER
1010 TK = 0 : ST = 0 : LT = 23 : CD = WR :
REM "set to 1st track & sector
```

Other Versions

If you own one of the other two known versions of Zaxxon, you may have to use line

5010 or perhaps line 5020 for your sector edits. To activate these lines, remove line 5000 or line 5000 and line 5010.

Writing Super IOB Controllers

There seem to be many ways to create a Super IOB Controller text file and to integrate it with Super IOB. My favorite method is to write the controller on my word processor, AppleWriter //e, starting each new line with a line number and ending each line with a RETURN. Since my word processor produces standard text files, I have only to "EXEC filename" to load it into memory to find its checksums. To run Super IOB, I just have to "LOAD SUPER IOB", "EXEC filename", and then "RUN" the complete program. Pretty simple.

Super Controller

```

1000 REM SUPER CONTROLLER
1010 TK = 0 : ST = 0 : LT = 35 : CD = WR :
REM "set to 1st track & sector
and to 1 track past the last one
to be copied (tracks 0-34 here).
1020 T1 = TK : GOSUB 490 : REM "start
of reading cycle...toggle
command to read.
1021 REM RESTORE : REM "use this
command ONCE if you use lines
1022, 1023, 1024, or 1026 below
(if you use any DATA
statements).
1022 REM GOSUB 190 : REM "to use
altered address marks...use
data statement in 62010 and line
1065 to normalize the writing
back to disk.
1023 REM GOSUB 210 : REM "to use
altered data marks...use data
statement in 62010 and line 1065
to normalize the writing back to
disk.
1024 REM GOSUB 170 : REM "to use
altered address field and data
field ENDING MARKS. Use only the
first two bytes of each in data
statement at line 62010 and
include all four even if you only
need to change one. Use line 1065
to normalize.
1025 REM GOSUB 270 : REM "to ignore
the address checksums.
1026 REM GOSUB 290 : REM "to use
altered data checksums. The
normal value is 0. Put the new
value in the next data statement
(line 62010) and use line 1065
below to normalize the writing
to the disk.
1027 REM GOSUB 360 : REM "for an RWTS
swap routine. RWTS must be
BLOADED by a line 10010 below.
1028 REM POKE 47405 , 24 : POKE 47406
, 96 : POKE 47497 , 24 : POKE 47498
, 96 : REM "to ignore checksums
and end marks...Use line 1069 to
normalize.

```

```

McFadden

The Print Shop
Broderbund Software
17 Paul Drive
San Rafael, CA 94903
\$50.00

Requirements:

Apple II series computer, 48K RAM
minimum
Super IOB v1.2
A blank disk
RESET capability optional

After buying The Print Shop about a month ago on the advice of a friend, I became immediately intrigued by the possibilities of the program. Even though The Print Shop will make one backup copy of itself, due to the amount of disk access the program does, my first priority was the deprotection of this disk.

Format of the Disk

When I examined the disk with my sector editor (Tricky Dick), I was pleasantly surprised to find that most of it (tracks \$0

through \$21) were encoded under completely normal DOS 3.3. Only track \$22 was written in a nonstandard format. I assumed that this track was utilized for a nibble count.

After quite a bit of disk snooping I found that The Print Shop disk contains a basically standard DOS 3.3 fastloader which uses normal address (D5 AA 96) and data headers (DE AA) on tracks \$0 thru \$21 (Hex). **The DOS, however, is not in its normal location. If you take a tour through the disk with a sector editor you will find DOS on track \$0 sectors \$0 to \$3 and track \$F sector \$0 thru track \$10 sector \$3.** You can move this code back to the normal DOS location if you desire but there is really no need; the computer does not care where the operating system is located. The Print Shop DOS uses a bit of self-modifying code and has a few changes to such things as the reset vector and VTOC (more on this later), but generally these have little, if any, effect on the operation of the system. That is until we consider track \$22 (Hex).

Track \$22 has been written in a very strange format. On a new Print Shop disk there are three sets of bytes inserted into track \$22 (I can't really call them headers), along with a lot of garbage with no apparent organization. The first of this sequence of bytes, A5 DF D4, shows that this disk has not been copied. When the built-in copy program is run, these bytes are overwritten and no more copies will be allowed. The second set of bytes on track \$22 are F5 AA 00. These bytes identify the disk as a master or copied disk. The third set, D5 DE D4, is used by the nibble count routine.

Finding the Nibble Count

Once I had discovered that track \$22 was being used for the nibble count, all that I had to do was to track down the code that was performing the nibble count and somehow bypass it. This required quite a few hours of staring at my computer's monitor.

If you boot up with DOS 3.3 and then try to catalog The Print Shop disk, all you'll get is a message from the authors of the program. This is because DOS 3.3 expects to find a VTOC (Volume Table of Contents) on track \$11, sector \$0. Bytes \$1 and \$2 (the first byte is \$0) of a VTOC point to the first directory sector. On The Print Shop disk this points to track \$11, sector \$1, which contains the message from the authors interspersed with a bunch of control characters that cause the screen to scroll up. However, The Print Shop DOS has been modified so that its real VTOC is on track \$11, sector \$2. So, to catalog the disk from DOS 3.3 you have to do a POKE 45069,2 (B00D:02 from the monitor). This will allow you to view the real directory which has 34 files in it, one of which is a binary file called HELLO. I found that I could BLOAD this file from normal DOS and by examining the contents of AA60.AA61 and AA72.AA73, I discovered that it is loaded at \$800 and is \$7FC bytes long. For obvious reasons, I assumed that HELLO would be the boot-up file.

Continuing on with my investigation of The Print Shop, I found that if it were copied with a copy program that ignored the errors on track \$22, the copy would proceed through the majority of the boot before

- 2) Run Super IOB and follow the prompts to copy The Print Shop to an initialized disk.
- 3) Insert the Super IOB copy of The Print Shop into your drive and remove the call to the nibble count routine by typing

BLOAD MENULIB

CALL -151

7806:EA EA EA

BSAVE MENULIB,AS6000,LS21F8

- 4) Remove the access to the built-in copy program by typing

BLOAD HELLO

840:A9 01

BSAVE HELLO,AS800,LS7FC

Your deprotected copy of The Print Shop should now have about 22 free sectors available for your own use. — IT WORKS —

ADVENTURE TIPS ADVENTURE TIPS

Colossal Caves

Adventure International

You need keys to unlock the grate. Look in the well house. Birds are natural predators of snakes. Drop it. Can't cross the fissure? You need something from the debris room. Grease up that iron door with oil from the east pit. It should open easily, now.

*** Ultima III**

Origin Systems

To find the town of Dawn (and get exotic weapons) you must begin at Lord British' castle. Go West-8, South-35 and wait for the moon cycle to reach (0)(0). Then type, E.

**Contributed by Robert Ellerby.*

Time Zone

Sierra On-Line

Can't satisfy Her Highness, Cleopatra? Check the perfume counter in a European department store in 1700 A.D.

You can't use, "Open sesame" to get into the pyramid. Climb the back side, instead.

You'll find great wealth hidden in the pyramid. Don't leave a single stone unturned.

Get the shovel from the rock garden. You'll find a valuable item in the rice garden if you do some digging.

Deal carefully with the peasant. He sells wares only for the right price.

Zork I

Infocom, Inc.

Looking for anything special? You'll find something in the tree tops.

Only a delicate touch will open the egg without ruining it. Let the master of burglary do it for you.

Don't bother with the door to the house. Be creative.

Every self respecting house has a dungeon under it, doesn't it? You'll find the entrance hidden in the living room. The trap door will keep you locked in the dungeon until you explore it and find another way out, so don't waste your time trying to get it open.

Ulysses & The Golden Fleece

Sierra On-Line

The castle guard is a pretty nasty guy.

If he asks you a question, it's best to answer truthfully.

Before going out to sea, you must get the map from the dock guard. Without it, the hurricane will sink you for sure. To outwit your fine feathered friends, "go island" to find all your stolen possessions.

The empty bottle should help quench your thirst at the island spring.

Transylvania

Penguin Software

You might need some of the items in the shack at some time later.

Look for a hidden room at the log cabin. The deer antlers hold the clue. Don't be queasy about opening the coffin.

What's a hut without "three blind mice"? You'll find them in the wagon. You will face the perils of the cemetery much better with a cross of your own. Take it and then move the gravestone.

Pirate Adventure

Adventure International

Don't be out on the ledge without good reading material.

The torch will light your way but you'll need matches from the apartment. Try the bag.

Brute force won't work to open the chest. Check out the rug in the apartment first, but make sure you bring along a hammer.

Crocodiles eat seafood, don't they? What better way to distract them?

Mission Asteroid

Sierra On-Line

The explosives must be set to blow at a certain time. Try a few to see which one works.

Only a more "in depth" study of the asteroid will reveal the correct place to set off the explosives.

Still looking for the right place to set the explosion? Drop them in the pit.

Adventureland

Adventure International

What's the magic word for using the ax? "Bunyon", of course.

If you've lost the ax, check out the hidden grove.

Need someplace to store all your treasure? Tree climbing is never out of season.

"Scream" loudly to become "unbearable".

ne of the best features of The Print Shop by Broderbund is the ability to create graphics and store them on an unprotected diskette so that they can be used for letterheads, greeting cards, banners, etc. Unfortunately, the graphic editor supplied by Broderbund is not of superior quality. If you are using the keyboard, it is particularly unfriendly. To make a long story short, there are several graphic editors on the market (The Micro Illustrator and The Graphics Magician, for example) which offer more versatility.

Wouldn't it be great if you could design a graphic image using your favorite editor and then use it with The Print Shop?

Or, how about capturing an image from a favorite game and using that as a graphic in The Print Shop?

Dream no longer! On the following pages you'll find The Graphic Grabber, a program designed to perform this very task! The Graphic Grabber can extract an image from any normally saved hi-res screen for use with The Print Shop.

Typing It In

Use the procedure outlined on the page opposite the contents page to type in the BASIC program list-

ing and also the Hexdump at the end of this article. Save the BASIC program with:

SAVE GRAPHIC GRABBER

Save the Hexdump with:

**BSAVE OBJ.GRAPHIC GRABBER,
AS4000,LSE2**

Using The Graphic Grabber

When The Graphic Grabber is RUN, the hi-res screen page 1 is not altered. This is so that you may use what is currently on the screen as a graphic rather than going through the step of saving the hi-res screen and then

later loading it again (although you may do it this way if you wish).

There should be a flashing rectangle in the center of the screen and at the bottom of the screen there should be a list of commands. Think of the rectangle as a window. Everything inside this window and pixels behind the edges of the window itself will be saved when you use the "SAVE WINDOW" option. The maximum size graphic that can be transferred to The Print Shop is 88 x 52 pixels.

Moving the Window

Motion is accomplished by using the standard ESCape keys. Pressing the keys "I,J,K,M" will move the window up, left, right and down respectively.

Toggle Text

This option is invoked by pressing the spacebar. It will either make the command menu visible or invisible. When the command menu is invisible, the bottom 32 lines of the hi-res screen are visible.

Load Screen

If you type "L", an entire normally

* The Graphic Grabber For The Print Shop

By Ray Darrah

BSAVEd hi-res picture will be loaded. When you are asked for the filename, a special disk access routine is invoked. You may press ESC to abort the Load Screen option. If you type a null as the filename, then a CATALOG will be displayed. You may specify Slot, Drive and Volume parameters by including them in the filename. For example, if you typed

EXODUS1,D2

as a filename, the file EXODUS1 would be loaded in to the hi-res screen from drive 2. This also works for the directory function. If you want a directory of a different disk, simply make the first character a comma. For example, if you typed

,S6,D1

as a filename, the CATALOG of the disk in slot 6, drive 1 would be displayed.

Save Window

Pressing RETURN will invoke the save window routine. This also uses the special disk access routine mentioned above. The only difference is that the graphic inside the window is saved rather than a whole hi-res picture loaded.

Print Mode

The print mode is the manner in which the screen will be printed by The Print Shop. When the words "Print Mode" are inverse, dots on the screen which are lit ("on") be printed as black on your paper. When the words "Print Mode" are normal, then the lit dots on the screen will be white (not printed) on your paper. The print mode is toggled by pressing "P".

Leaving The Program

You may leave the program by pressing ESC. If you should accidentally escape from The Graphic Grabber, a RUN will get things going again. Nothing except the window's position will be changed when you restart the program this way.

A Bit About Graphics

A graphic created with the graphic editor section of The Print Shop (or the Graphic Grabber) is a normal Binary file with an address of \$5800 and a length of \$240. However, The Print Shop will recognize any normal Binary file that is four sectors long as a graphic.

The first 572 (or \$23C) bytes define the graphic and the rest are ignored. These bytes are arranged as fifty-two rows of eleven bytes. Each bit in the rows corresponds to a dot with the most significant bit of each byte being the leftmost dot. A one bit is a black dot and a zero bit is a white dot. Row two sequentially follows row one. This

Hardcore COMPUTIST welcomes articles of interest to users of the Apple II (or compatible) computers and would like to publish well-written material including:

- * Softkeys
- * Hardware Modifications
- * Advanced Playing Techniques
- * DOS modifications
- * Utilities
- * Product reviews
- * Adventure Tips
- * Original programs
- * Do-it-yourself hardware projects
- * General interest articles
- * Bit-Copy Parameters

Send your submission on a DOS 3.3 disk using an Apple (or compatible) editing program. Enclose a double-spaced hardcopy manuscript (typewritten or computer printed). Submissions will be returned only if adequate packaging is enclosed.

**Have you
written
an ARTICLE or
PROGRAM
you'd like to see
published in
Hardcore
COMPUTIST?
We would like to hear
from you!**

Hardcore COMPUTIST pays on publication. Rate of payment depends on the amount of editing necessary and the length of the article- generally between \$10 for a short softkey, and \$50 per typeset page for a full-length article. For a higher pay rate, enclose the original commercial disk for verification of softkeys. We guarantee the disk's return.

Softkey Publishing buys all rights as well as one-time reprint rights (for upcoming BEST OF Hardcore) on general articles, and exclusive rights on programs. However, alternate arrangements may be made with individual authors, depending on the merit of the contribution.

For a copy of our WRITER'S GUIDE, send a business-sized (20-cent) SASE (self-addressed, stamped envelope) to:

PART TWO:

The Lone Catalog Arranger v1.0

By Ray Darrah

Requirements:

Apple][Plus with slot 0 RAM card or
Apple //e
One disk drive with DOS 3.3
An accurate typing hand

This article describes the final portion of a program called The Lone Catalog Arranger (henceforth referred to as LCA). As you may remember from the article which appeared in Hardcore COMPUTIST No. 16, LCA was designed for the manipulation of DOS 3.3 disk directories. With this program you can:

- 1) View the free and used space on a disk
- 2) Undelete, Delete, Lock and Unlock files

- 3) Insert and see illegal characters in filenames
- 4) Change the order of the files in the CATALOG
- 5) Remove deleted files from the directory
- 6) Create dazzling titles for your disks

The program is comprised of two parts: An Applesoft BASIC program and a Machine Language program. *Due to space limitations, only the BASIC portion of the program was presented in the previous issue. This is the machine language portion that was missing from Hardcore COMPUTIST No. 16.* Please note that this program *does* require the BASIC program in Hardcore COMPUTIST No. 16.

Typing It In

The machine language portion of LCA is very special. It was designed to be combined with the Applesoft portion of LCA in order to form one file that can be RUN. In order to do this, you must follow these steps:

- 1) Clear the program in memory via DOS
FP
- 2) Enter the monitor
CALL-151
- 3) Key in the hexdump at the end of this article and save it
BSAVE OBJ.LONE ARRANGER,
AS800,LS1DF
- 4) Pop back into BASIC
E003G
- 5) Start the program and change the beginning of program pointers
RUN
- 6) Load in the BASIC portion of LCA that you saved from Hardcore COMPUTIST No. 16
LOAD BAS.LONE ARRANGER
- 7) Start up this part of the program
RUN
- 8) As soon as the title page appears press ESC to leave the program.
- 9) Save both the machine language and the BASIC portions as one file

SAVE LONE ARRANGER

The One File Concept

As indicated in Step 9, both the machine language program and the BASIC program are saved as one Applesoft file. Here is an explanation of how this is accomplished. If you are a new computist, you may get a little queasy during this explanation, but try to hang in there anyway.

First of all, any BASIC program in memory was cleared with an "FP". This has the effect of restoring the beginning of program pointers (\$67 and \$68 or 103 and 104) to \$801 or 2049. This is the usual starting place of BASIC programs. It just so happens that the machine language part of LCA starts at \$800 or 2048, one byte before this address. The first 15 bytes of the program are designed to look like a BASIC program at \$801 or 2049. That is why, after keying in the hexdump, a LIST will reveal:

10 CALL 2063 : RUN

The RUN command in Step 5 executes this artificial program. The CALL 2063 in the program executes a real machine language program starting at \$80F or 2063. This program changes the beginning of program pointers to point just beyond the end of the

machine language routines. Therefore, the LOAD command of Step 6 puts the BASIC portion of the program directly above the machine language program. This program is then executed in Step 7. When you press ESC, the real BASIC program puts the pointers to beginning of BASIC back to \$801 or 2049. Since the end of program pointers have remained unchanged, memory from \$801 all the way to the end of the BASIC portion is saved with the SAVE command of Step 9.

This is illustrated in the following diagram:

```

*****
* Addr. * Function *
* * *
* $0800 * Must be a zero so that BASIC *
* $0800 * will work. *
* * *
* $0801 * Artificial BASIC line which *
* $080E * calls $080F and then RUNS. *
* * *
* $080F * Copies ROM into the 16K card *
* $082F * so that BASIC can be modified.*
* * *
* $0830 * Sets start of BASIC program *
* $0838 * pointers to $09DD. *
* * *
* $0839 * Machine language routines *
* $09DB * that are used by BASIC LCA. *
* * *
* $09DC * When start of BASIC program *
* $09DC * pointer is set to $9DD, this *
* * * byte is just like $0800 (00). *
* * *
* $09DD * A couple of zeroes that *
* $09DE * indicate this as the end of *
* * * the BASIC program. These *
* * * zeroes will be changed when a *
* * * program is LOAded. *
* * *
*****

```

A Word About The ML of LCA

To gain a better insight of LCA operation, a discussion of the main machine language subroutines follows. If you get weak in the knees whenever machine language is discussed, you may wish to skip this part. I put the machine language program at \$0800 because the routines quickly exceeded the \$D0 length limit imposed upon code placed in page \$03 of memory.

Copy ROM Into Language Card

This routine spans from \$80F to \$82F and is called only once when LCA is first run. The rare occurrence of two consecutive LDA instructions to ensure that the language card is configured so that memory reads return the ROM values and memory writes are stored into the language card RAM. The entire ROM image is then stored into the language card RAM. This is necessary because of several routines in the BASIC portion of LCA that modify BASIC. One example of this is line 840. The modification performed in this line alters BASIC so that it allows normal, inverse and flashing

CORE

characters to be printed simultaneously. The "X=" statement of line 1320 configures the language card so that its RAM is both readable and writable. The language card stays this way while LCA is running.

Move Beginning of BASIC Program Pointers

This routine is also called only once when LCA is first run. It spans from \$830 to \$838 and sets the beginning of program pointer to \$9DD. This is where the BASIC portion of LCA begins.

Call RWTS

This routine occupies memory from \$839 through \$84C and exists only because DOS does not allow an easy method to call the RWTS directly from BASIC. BASIC routines that use this ML routine are "DELETE SUBROUTINE", "EXHUME SUBROUTINE", and "BUILD DIRECTORY". These routines alter the IOB parameter list in DOS (starting at location \$B7E8 or 47080) before calling "CALL RWTS". The ML routine calls the RWTS with the 6502 registers set correctly and, if an error occurs, invokes a BASIC error which will then be handled by an ONERR GOTO statement.

Show Controls As Inverse

This routine exists as an interceptor between the program that is printing and the actual COUT routine. It spans from \$84D to \$859 and is used whenever control characters are to be displayed as inverse characters. An example of this is when the directory is displayed during LCA execution.

Collect Files Into FS(XXX)

Memory addresses from \$85A through \$891 are occupied by this routine which is used by "NEW CATALOG ROUTINE" to store the directory into the locations in memory where the FS array is stored.

New Catalog Routine

This routine spans from \$892 through \$910 and is used to read the directory. By using "COLLECT FILES INTO FS(XXX)", this routine stores the directory into an array so that BASIC can manipulate it. The current variable pointer must have been previously set (the FS(0)=" " statement in line 1500) to the array that is to hold the directory. It is very similar to the CATALOG routine in DOS. The strings that are sent to "COLLECT FILES INTO FS(XXX)" are identical to the file entries that a CATALOG command would produce, with two exceptions. First of all, deleted files are not omitted and are preceded with a hyphen.

Continued on next page

Secondly, the last two characters of each string correspond to the track/sector list pointer of the file.

Print A Bunch Of Strings USR

This is the routine that is responsible for displaying a portion of the directory during most of LCA. It is designed to hook up to the USR command and occupies memory from \$911 through \$985. It assumes that the first array is the array that you wish to display. It evaluates the expression between the parenthesis in the USR command and puts that array element at the top of the list. VTAB position number 10 is inverted by the statements at \$95A through \$95F. A blank line is printed before the first element and after the last one which allows scrolling without leaving traces.

Test Whether A Sector Is Free

Spanning from \$986 through \$994, this routine examines the last used VTOC map (stored in DOS at location \$B3BB) to test whether the sector specified by memory locations \$FE and \$FF is used or not. The answer is returned in memory location \$FD.

Free A Sector

This routine which occupies memory from \$995 through \$99E alters the last used VTOC map (stored in DOS at location \$B3BB) so that the sector specified by \$FE and \$FF is unused. This routine is used by the "DELETE SUBROUTINE" of the BASIC portion of LCA.

Allocate A Sector

This routine resides at \$99F through \$9AA and is similar to the above routine except that it marks the specified sector as used. It is used by the "EXHUME SUBROUTINE" of the BASIC portion of LCA.

Blank The Catalog

Spanning from \$9C3 through \$9DB, this routine is called just before the new directory is created. It zeroes memory from \$8100 through \$8F00. This is where the new directory is stored as it is created by the "BUILD DIRECTORY" subroutine of the BASIC portion of LCA. Each page of memory corresponds to a sector of the directory.

Enough About The ML. What About Updates???

In the future, I intend to update this program to make it function more quickly and be more user friendly. In the meantime, I'm hoping this program will prove helpful to you. I would like to hear from those readers who have ideas about what they would like to see happen to The Lone Catalog Arranger.

Bugs From Hardcore COMPUTIST No.'s 15 & 16

Hardcore COMPUTIST No. 15

Boot Code Trace For Tic Tac Show, pg.

25: Line 10 of the short HELLO program that appears in Step 14 should be as follows

```
✓ 10 ON PEEK (104) = 96 GOTO 20 :
   POKE 104,96 : POKE 24576,0
   : PRINT CHR$(4) "RUN
   ^HELLO"
```

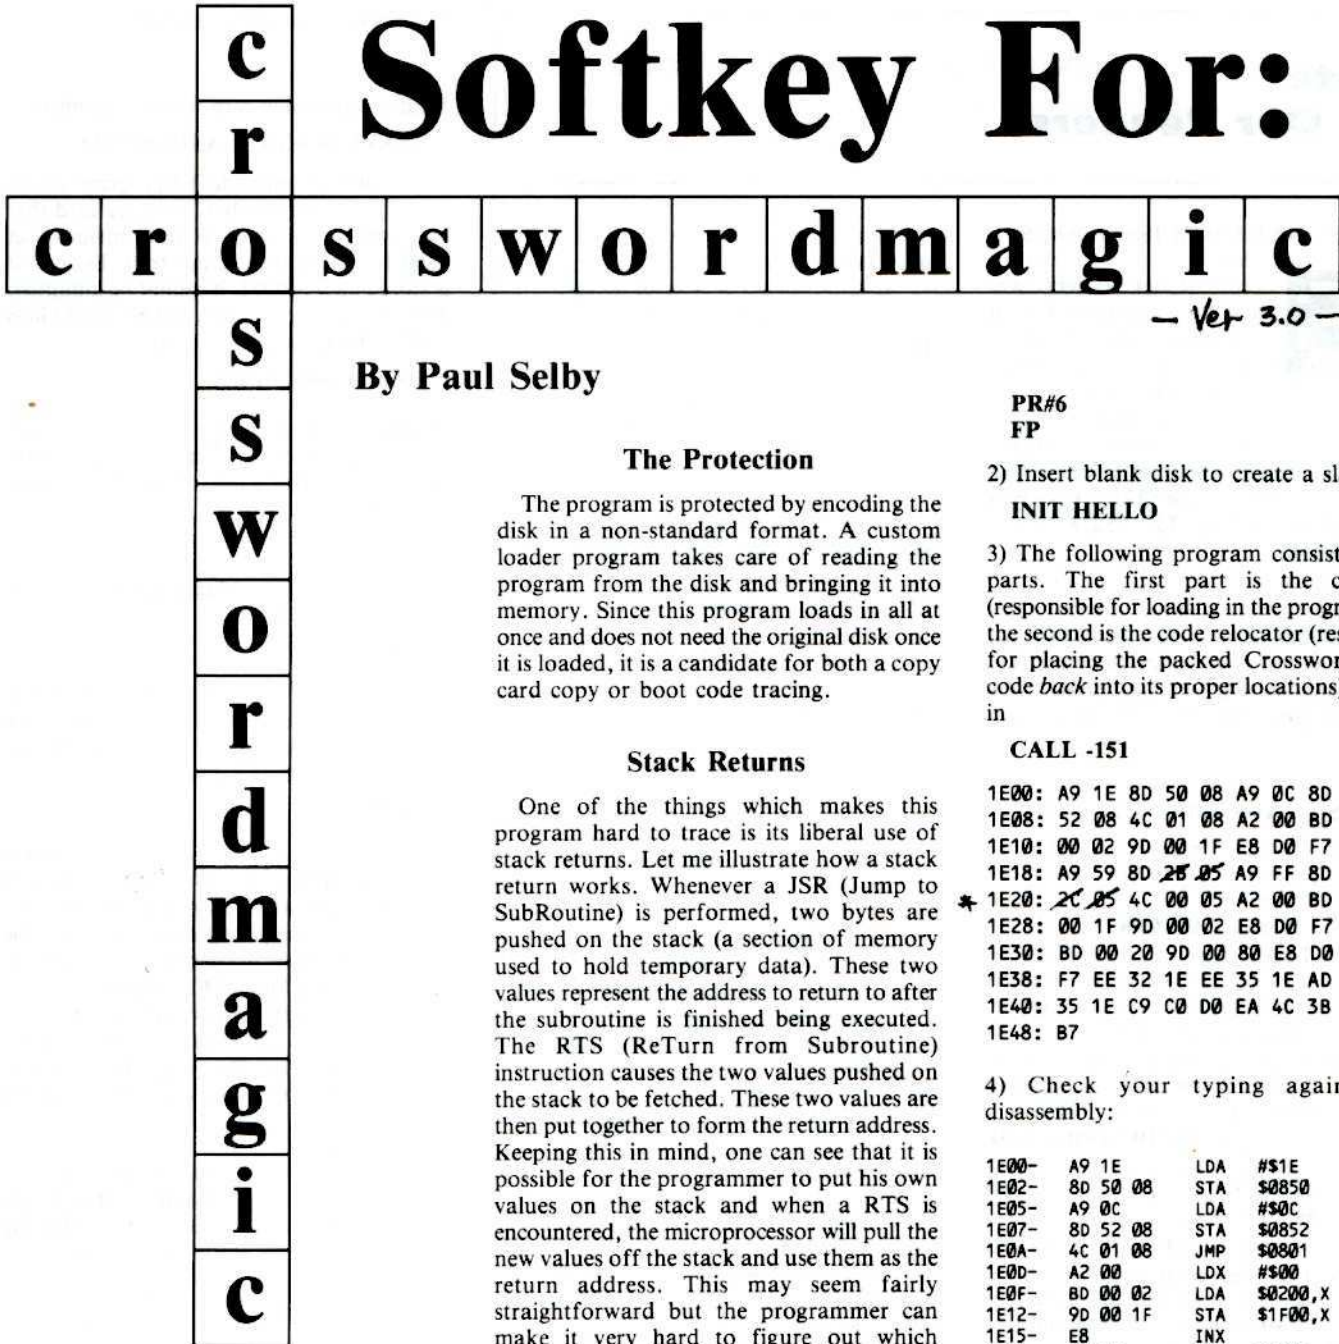

Hardcore COMPUTIST No. 16

✓ **Rescue Raiders Softkey, pg. 6:** The values in the Track column of the table in Step 4 should all be \$0E (not \$18 as shown in the last two lines). Likewise, the values in the Sector column should all be \$0B (not \$02 as shown in the last two lines).

The Controller Writer, pg. 17: The values in the last two lines of the Electronic Arts Controller screen dump should be

```
TRK- $02 SCTR- $03 BYTE- $47 TO- $AA
TRK- $02 SCTR- $03 BYTE- $51 TO- $AD
```

Softkey For:

- Ver 3.0 -

By Paul Selby

The Protection

The program is protected by encoding the disk in a non-standard format. A custom loader program takes care of reading the program from the disk and bringing it into memory. Since this program loads in all at once and does not need the original disk once it is loaded, it is a candidate for both a copy card copy or boot code tracing.

Stack Returns

One of the things which makes this program hard to trace is its liberal use of stack returns. Let me illustrate how a stack return works. Whenever a JSR (Jump to SubRoutine) is performed, two bytes are pushed on the stack (a section of memory used to hold temporary data). These two values represent the address to return to after the subroutine is finished being executed. The RTS (ReTurn from Subroutine) instruction causes the two values pushed on the stack to be fetched. These two values are then put together to form the return address. Keeping this in mind, one can see that it is possible for the programmer to put his own values on the stack and when a RTS is encountered, the microprocessor will pull the new values off the stack and use them as the return address. This may seem fairly straightforward but the programmer can make it very hard to figure out which numbers are pushed on the stack. Without knowing which values are placed there, it becomes almost impossible to trace the program flow.

To copy Crossword Magic, it is necessary to write a controller program which will monitor and modify the loader program. These modifications will take advantage of the stack returns by changing the values pushed on the stack. These values would then point back to the controller so that more values could be pushed on the stack and eventually jump to the monitor. In addition, the self volatile memory areas have to be relocated to a safe position.

The Procedure

1) Boot System Master to load DOS and then clear memory

PR#6
FP

2) Insert blank disk to create a slave disk

INIT HELLO

3) The following program consists of two parts. The first part is the controller (responsible for loading in the program), and the second is the code relocater (responsible for placing the packed Crossword Magic code back into its proper locations). Type it in

CALL -151

Crossword Magic Version 3.0
L & S Computerware
1008 Stewart Drive
Sunnyvale, California 94086
(408) 738-3416
\$49.95

Requirements:
48K Apple][Plus or equivalent
DOS 3.3 System Master
One Blank Disk

 Crossword Magic is a fantastic program which will create a crossword puzzle using your words and clues. Once created, your puzzle may be played on the screen or a hardcopy version may be produced.

Continued on next page

Note To Our Readers:

(REPRINT FROM ISSUE No. 5)

Several of our readers have called or written to ask what assembler was used to produce source code listings printed in Hardcore COMPUTIST. The answer to this question is that we use the S-C Macro Assembler from the S-C Software Corporation (2331 Gus Thomasson, Suite 125, PO Box 280300, Dallas, TX 75228, Cost: \$80.00).

To convert the source files published in our magazine to a format that is compatible with the particular assembler that you use, consult the following list of S-C Assembler directives:

S-C Assembler Directives:

- .OR** - ORigin. This sets the address of program origin to the value of this expression.
Example: **.OR \$300**
- .TA** - Target Address. This sets the location or Target address at which the object code will be placed during assembly.
Example: **.TA \$4000**
- .TF** - Target File. This directive causes the object code to be stored to disk rather than in memory during assembly.
Example: **.TF CHECKERS GAME**
- .IN** - INclude. This causes the contents of the specified source file to be included in the assembly.
Example: **.IN CHECKER BOARD**
- .EN** - ENd of program. This is an optional directive which indicates the end of the source code to be assembled.
- .EQ** - EQuate. Defines a label to have the value of the expression.
Example: **COUT .EQ \$FDED**
- .DA** - DAta. Creates constants or variables in the program.
- .HS** - Hexadecimal String. This directive converts a string of hex characters to binary and stores them at the current location in memory.
- .AS** - ASCII String. Stores the binary equivalent of the ASCII characters in quotes.
Example: **.AS "APPLE II"**
- .AT** - ASCII Terminated. This operates the same as .AS except that the high-order bit of the last character in the string is set opposite to that of the preceding

characters.

- .BS** - Block Storage. This reserves a specified number of bytes for storage.
Example: **.BS 6**
- .TI** - Title. This is used to print a program title and page number at the beginning of each page during assembly.
- .LI** - LIst control. Controls whether a program listing will be generated during assembly. The listing can be either turned on or off.
Example: **.LI OFF**
- .MA** - MAcro definition. Beginning of Macro definition.
- .EM** - End Macro definition.
- .US** - USer directive. Allows the user to indirectly jump to a set of user-supplied instructions.
- .PG** - PaGe control. Prints an ASCII form feed character during assembly.
- .DO** - DO conditional assembly. If the value of the expression following the DO statement evaluates true, then the code up to the .FIN directive will be assembled. Otherwise, it will be ignored.
Example:
FLAG .EQ 1
.DO FLAG
- .FIN** - FINish conditional assembly. Indicates the end of the code to be assembled under conditional assembly.
- .ELSE** - This is used to introduce an IF-THEN-ELSE structure into portions of source code affected by conditional assembly.

In addition, the S-C Assembler uses a pound sign (#) to indicate the lower byte of a label's address and a slash (/) to indicate the upper byte of a label's address.

Example: **LDA #COUT**
LDX /COUT

We are now using a standard version of the S-C Assembler but, in the past, several source files produced by a custom version of the assembler managed to slip by our staff and were published in Hardcore. As a result, some source code listings contained BGE (Branch on Greater or Equal) and/or BLT (Branch on Less Than) instructions. To make these source files compatible with your assembler, convert BGE to BCS and BLT to BCC.

Continued from previous page

5) Save program in case you make a mistake
BSAVE MAGIC 1,AS1E00,LS49

6) The initial boot code is a program stored on a PROM on the disk interface card that reads track 0 sector 0 into memory at \$800-\$8FF and then jumps to it. Because it is stored on a PROM, it cannot be modified. To remedy this, the code will be moved into RAM where it can be modified
6600 < C600.C6F8M

7) The jump out of the bootstrap loader normally goes to \$801. The following change will make control jump to \$1E00, the loader program
66F9:00 1E

8) Insert Crossword Magic disk and execute the boot
6600G

9) At this point the computer will be in the monitor and the drive will be spinning. The following command will stop the drive to prevent wear on the disk
C0E8

10) The Crossword Magic program actually uses track \$10 sector \$0 as the VTOC (the disk map of what parts of the disk are occupied by programs) and also stores the printer data here. To correct this situation, the Crossword Magic DOS must be patched so that it will use the normal track \$11 and sector \$0 for the VTOC. This can be accomplished by changing the value at \$AC01 from a previous value of \$10 to a \$11
AC01:11

During the remainder of the procedure, to compress Crossword Magic so that it will take up less disk space, the following memory locations will be relocated:

Original Location	Relocated Location	Length
\$0200-02FF	\$1F00-1FFF	\$0100
\$0800-10FF	\$0800-10FF	\$0600
\$6000-7FFF	\$6000-7FFF	\$2000
\$8000-9AFF	\$2000-3AFF	\$1800
\$9000-BFFF	\$3000-5FFF	\$2300

11) Next, relocate most of DOS so that it won't be overwritten on the next boot
2000 < 8000.BFFFM

12) The code at \$800-\$8FF must be moved to a temporary place so it will be safe when the slave disk is booted (this area is also overwritten when a boot is performed)
3B00 < 800.8FFM

13) Boot the slave disk so the program can be saved
6^{CTRL}P

14) Move back the code which was at \$800-\$8FF

CALL-151
800<3B00.3BFFM

15) Now set up a location so that when the program is BRUN it will jump to \$1E25 where the code relocater resides

7FD:4C 25 1E

16) Save the CROSSWORD MAGIC program

BSAVE MAKER,AS7FD,LS7803

17) Although the CROSSWORD MAGIC program has been copied, the files which support the program must also be copied. There are three files on the disk:

1. USER*
2. Z<CTRL>Z>
3. CROSSWORD MAGIC DEMO

The first file is the user-written printer dump program, the second file holds the names of the puzzles, and the last file is the demo puzzle.

Use FID on the system master to copy these files to the slave disk.

Getting The Other Side

Although the player side can be copied by COPYA, it can also be copied by boot code tracing. By doing this, the player and the maker can occupy the same disk with room to spare.

18) Enter the following program:

```
1800: A9 18 8D 0B 08 A9 0C 8D   $CD79
1808: 2C 08 4C 01 08 A9 1A 8D   $BD93
1810: B8 04 A9 18 8D B9 04 4C   $0AB9
1818: 7E 04 4C 59 FF A2 00 BD   $E025
1820: 00 19 9D 00 60 E8 D0 F7   $521D
1828: EE 21 18 EE 24 18 AD 24   $146F
1830: 18 C9 68 D0 EA BD 00 21   $C865
1838: 9D 00 7F E8 D0 F7 EE 37   $2A6B
1840: 18 EE 3A 18 AD 3A 18 C9   $A81A
1848: 96 D0 EA BD 00 38 9D 00   $8B27

1850: 9D E8 D0 F7 EE 4D 18 EE   $82E6
1858: 50 18 AD 50 18 C9 C0 D0   $A785
1860: EA 4C 3B B7                $7EDF
```

19) Check your typing against this listing.

```
1800- A9 18      LDA #S18
1802- 8D 0B 08  STA $080B
1805- A9 0C      LDA #S0C
1807- 8D 2C 08  STA $082C
180A- 4C 01 08  JMP $0801
180D- A9 1A      LDA #S1A
180F- 8D B8 04  STA $04B8
1812- A9 18      LDA #S18

181D- A2 00      LDX #S00
```

Continued on next page

Whiz Kid by Ray Darrah

page 26
The following article is a continuation of the Whiz Kid article which appeared in Hardcore COMPUTIST No. 15.

If you haven't read that article, I suggest you do so immediately. If you have read the article, you may want to read it again to refresh your memory.

As demonstrated by the BASIC program in the previous article, moving the disk arm is a simple procedure. Because of the relative nature of disk arm movement, the current phase that the disk arm is over must be known. DOS uses several memory locations on text page 1, that aren't displayed in the 40 column by 24 row display, to keep track of the current phase of every disk arm connected to your computer.

To move the disk arm, you should follow these steps:

- 1) Turn the drive on.
- 2) Turn on an adjacent magnet (the magnet turned on depends on which way the head is to be moved).
- 3) Wait a while so that the shaft will become aligned.
- 4) If you are not at the destination phase then go to Step 2.

BASIC Movements

The most crucial step in the head movement algorithm is the delay routine that waits while the shaft of the stepper motor aligns itself with one of the magnets. DOS has a table of values at \$BA11-\$BA28 that are used by the SEEKABS routine at \$B9A0 to generate these delays. To speed up the movement of the head, this table contains values that generate delays which are inversely proportional to the velocity of the motor's shaft. In other words, the first wait that DOS performs is the longest and the wait is reduced for each new magnet. Using this method, DOS moves the drive head at the fastest possible rate.

The BASIC program from the last issue can reliably move the drive head because the BASIC interpreter is so slow that no delay routine is necessary.

The following is an explanation of how this BASIC program functions:

Line 10 clears the screen, puts the drive slot number in SL and puts the drive number in DR.

Line 20 puts the current phase in CP and puts the destination phase in DP.

Line 30 puts the beginning address of the control registers for the specified drive in AD, turns on the power to the drive(s) by referencing register 9 (\$C0n9) and engages the proper drive

by referencing either register 10 or 11 (\$C0nA or \$C0nB) depending on the setting of DR.

Line 40 compares the current phase to the destination phase. If they are the same it exits via line 110.

Line 50 determines which direction the drive head has to move by comparing the destination phase to the current phase. If the drive head has to move toward higher tracks, then execution continues at line 80. Otherwise, execution continues at line 60.

Line 60 sets up a loop to count downwards, by one, from one more than twice the current phase to twice the destination phase.

Line 70 references the next register to either turn on or off the current magnet, gets the next element in the loop and, when done, exits via line 110.

Line 80 sets up a loop to count upwards, by twos, from twice the current phase plus one to twice destination phase plus one.

Line 90 references the on register to determine which magnet the stepper motor shaft is to be aligned with next. Line 100 references the off register for the magnet that was turned on in line 90.

Line 110 references the motor off register for the specified drive and, therefore, turns off the drive and ends.

With a couple of changes, this program could easily be incorporated as a subroutine of a larger program that for some reason must manipulate the disk drive arm without going through DOS. Note: If you compile this program it probably will no longer work. This is because it depends upon the Applesloth interpreter for the necessary delays.

Quarter Tracks

* In my opinion, quarter tracks aren't worth much. DOS only writes on the even phases of the disk because the resolution of the drive head and the accuracy of the stepper motor are too poor to ensure accurate data on adjacent phases.

A quarter track is accessed by turning on two adjacent magnets in the stepper motor almost simultaneously. Since the shaft permanent magnet will be attracted to two energized magnets, it will be positioned in the middle of them, thus in-between phases. If data written on phase 0 will overwrite data written on phase 1, then imagine how much overlap there is between phase 0 and phase 0.5!

20) Save this second controller program

BSAVE MAGIC 2,A\$1800,LS64

21) Move boot code into RAM

6600 < C600.C6F8M

22) Change jump to point to controller

66F9:00 18

23) Insert the Crossword Magic player disk and execute its boot

6600G

24) Stop drive

C0E8

25) Patch DOS

AC01:11

For this side of the disk, memory will be compressed in the following manner:

Original Location	Relocated Location	Length
\$0800-17FF	\$0800-17FF	\$0800
\$6000-67FF	\$1900-20FF	\$0800
\$7F00-95FF	\$2100-37FF	\$1700
\$9D00-BFFF	\$3800-5AFF	\$2300

26) Compress the code

1900 < 6000.67FFM
2100 < 7F00.95FFM
3800 < 9D00.BFFF
6000 < 800.8FFM

27) Boot slave disk

6^{CTRL}P

28) Move the \$0800 code back

CALL -151
800 < 6000.60FFM

29) Set up jump at the beginning of the program

7FD:4C 1D 18

30) Save PLAYER program

BSAVE PLAYER,A\$7FD,LS4A05
5303

We're Done

This completes the softkey for CROSSWORD MAGIC. For those of you who would like to copy the logo, all that has to be done is to boot the CROSSWORD MAGIC disk and hit RESET the moment the logo appears, boot the slave disk, and type

BSAVE LOGO.MAKER,A\$900,LS5B5

The same applies to the player logo except you must type

BSAVE LOGO.PLAYER,A\$1400,LS5B0

To display the logos, just BRUN them. I also recommend the use of a fast DOS to speed up the loading time.

BACKUP PROTECTED SOFTWARE WITH COPY II PLUS™ 5.0

From the team who first brought you **COPY II PLUS** in 1981 comes a completely updated disk backup utility for your Apple II computer. New features include:

- Fully automatic bit copy. All parameters are stored on disk and are revised quarterly. Simply type in the name of the program you wish to backup, and **COPY II PLUS** does the rest!
- New utilities include Alphabetize Catalog, Fast 2-pass Disk Copy on a IIc or IIe, and an all-new Sector Editor.
- Supplied on a standard DOS diskette. Not copy protected, of course.

Increase the power of your APPLE II . . .

Use **COPY II PLUS™ 5.0**

Available at your local dealer or direct from us.

Current owners may update for \$20 with the return of your original disk.
